

Abstract

A remote-control transmitter for use with an electronic apparatus and a method of testing it are provided, which can be minimized in the cost of production and the overall duration of test. The transmitter has a microcomputer 11 to be shifted to a test mode when specific keys are pressed down and to store the opening-closing data of the keys closed after the test mode is initiated. The opening-closing data of the keys are then transferred as a remote-control test signal to a transmission circuit at once.
